Gestational Diabetes Mellitus

Gestational diabetes mellitus (GDM) is one of the most common medical complications of pregnancy. Debate continues to surround both the diagnosis and treatment of GDM despite several recent large-scale studies addressing these issues. The purpose of this document is to 1) provide a brief overview of the understanding of GDM, 2) provide management guidelines that have been validated by appropriately conducted clinical research, and 3) identify gaps in current knowledge toward which future research can be directed.

Background

Definition and Prevalence

Gestational diabetes mellitus (GDM) is a condition in women who have carbohydrate intolerance with onset or recognition during pregnancy. The prevalence of GDM varies in direct proportion to the prevalence of type 2 diabetes in a given population or ethnic group. It has been estimated that up to 6–7% of pregnancies are complicated by diabetes mellitus (DM) and that approximately 90% of these cases represent women with GDM (1). An increased prevalence of GDM is found among Hispanic, African American, Native American, Asian, and Pacific Islander women. With the increase in obesity and sedentary lifestyle, the prevalence of DM among reproductive-aged women is increasing globally.

Maternal and Fetal Complications

Women with GDM are at higher risk of gestational hypertension, preeclampsia (2), and cesarean delivery and

its associated potential morbidities. Most importantly, women with GDM have an increased risk of developing diabetes later in life. It is projected that up to 50% of women with GDM will develop diabetes 22–28 years after pregnancy (3, 4). The progression to type 2 diabetes may be influenced by ethnicity and the incidence of obesity. For example, 60% of Latin-American women with GDM may develop type 2 diabetes by 5 years after the index pregnancy (5).

The offspring of women with GDM are at increased risk of macrosomia, neonatal hypoglycemia, hyperbilirubinemia, operative delivery, shoulder dystocia, and birth trauma. The relationship between maternal hyperglycemia and fetal macrosomia, as well as other adverse outcomes, has been confirmed in the Hyperglycemia and Adverse Pregnancy Outcome study (6). This multicenter international study demonstrated a continuous relationship between maternal glucose levels and cesarean delivery, birth weight greater than the 90th percentile, clinical neonatal hypoglycemia, and fetal hyperinsulinemia. An increase in each of the three values on the 75-g, 2-hour

Committee on Practice Bulletins—Obstetrics. This Practice Bulletin was developed by the Committee on Practice Bulletins—Obstetrics with the assistance of Mark B. Landon, MD, and Wanda K. Nicholson, MD. The information is designed to aid practitioners in making decisions about appropriate obstetric and gynecologic care. These guidelines should not be construed as dictating an exclusive course of treatment or procedure. Variations in practice may be warranted based on the needs of the individual patient, resources, and limitations unique to the institution or type of practice.
