Time-Resolved Spectroscopy in Complex Liquids Renato Torre, 2007-11-27 The investigation of liquid properties is as old as the human desire to observe natural phenomena The paramount relevance of such state of matter is vious spanning from the basic theoretical model of random systems to the more advanced technical applications Nevertheless the interpretation and derstanding of liquid properties remains a challenge in materials science In the liquid state the potential and kinetic energies are characterized by similar values differently from the gas or solid crystal phases This fundamental physical property prevents a description of the liquid structure independently from its dynamics

The intermolecular forces and molecular motions are strictly interconnected producing the peculiar features of liquid phases In particular when the intermolecular potential is characterized by specific features as anisotropic and or long range interactions the liquid state shows cal dynamic aggregation and structuring phenomena This is the distinguishing characteristic of complex liquids Typical examples are the hydrogen bonded liquids glass formers polymers and liquid crystals Also relatively simple molecular liquids e g CS and benzene clearly show complex dynamics 2 evidence of local structuring effects During the last years researchers have undertaken a steady effort to improve the knowledge of liquid matter both from experimental and theoretical points of view New spectroscopic techniques based on nonlinear optical phenomena have been realized and applied to the study of simple molecular liquids On the other hand standard experiments have been applied to liquids characterized by particularly complex dynamic processes
